Hospital Connect — three-minute pitch

Target: about three minutes including the screen demonstration. Rehearse and shorten to your own speaking pace. Every patient example is fictional.

0:00–0:30 · The problem and the person

Imagine being the lead dispatcher for a rural BC community. You need a resource your local hospital cannot provide, but availability is scattered across calls and updates. Our team's hypothesis is that the coordination gap makes an already stretched service harder to run. We have secondary news context, but we have not interviewed a dispatcher yet.

0:30–1:00 · Our core idea

Hospital Connect is a shared fictional demonstration of one workflow: find an open facility with the required resource, request help, receive an offer, then accept and complete the coordination. We are not replacing emergency dispatch or making clinical decisions. The goal is to make the information and the next coordination step easier to see.

1:00–1:40 · Show the workflow

Here we select a generated patient example and answer the demo screening questions. The result explains exactly which rule set the priority; it is not trained AI. The recommendation lists the required resource and excludes a closed facility. We send a request using a case reference rather than the patient's identity. In the hospital dashboard, a matching facility offers availability, and the requesting team accepts it.

1:40–2:10 · Show data care and limits

Every identity in this demo is invented. Health identifiers use a DEMO prefix, contacts use example.test, and the importer rejects data outside the generated dataset. A duplicate-profile warning asks for human review; it does not call someone fraudulent or block coordination. Crew shift warnings and review timers are examples to discuss with users, not validated safety rules.

2:10–2:35 · Show the platform and payments

Piezas stores the shared records behind a server-only connection. The app keeps the workflow rules and minimises the network request. We can export the generated dataset as CSV, JSON and an Excel workbook. Worker-payment approval is explicitly a no-charge handoff demo: no gateway is connected, and we do not claim a payment was processed.

2:35–3:00 · What remains and what we ask

The app works as a coordination prototype, and its core journeys have automated browser checks. The next evidence step is an interview with a dispatcher or regional operations supervisor. Before any real use, we would need authorised staff access, verified capacity data, clinical review and a privacy assessment. Our ask is an introduction to that first user so we can test whether this workflow addresses the right problem.

Judge demonstration checklist

1. Create a fictional MRI case and explain its demo priority. 2. Close a matching facility and show it disappear from recommendations. 3. Send the de-identified resource request, switch to an open matching hospital, offer, accept and complete. 4. Show a duplicate-data review, downloadable dataset and no-charge payment history. 5. Open the interview gap and assumptions.
